

Afterplay

Afterplay remembers what made viewers come back, then plans one clear test for the next stream.

REMEMBER · TEST · LEARN

Creators can see what happened. They still have to guess what to do next.

What the tools show

A replay, clips, comments, and charts. Each lives in a different place.

What the next stream needs

Why did viewers care? What should carry into the next stream?
Which idea is worth testing?

The creator market is large. Attention and loyalty are scarce.

500 hrs/min

of new video is uploaded to YouTube.

<1%

regular viewers can make up less than 1% of viewers on newer or Shorts-heavy channels.

\$44B

projected U.S. creator ad spend in 2026.

~4%

of global creators earn more than \$100,000 a year.

Afterplay is built for growing gaming creators.

WHO USES AFTERPLAY

The primary user streams often but lacks a strategy team. Editors, managers, and creator programs share the same evidence and approval record.

CREATOR

needs a clear next move after each stream

TEAM

reviews evidence, clips, copy, and approvals

PROGRAM

supports many creators with one repeatable process

Find a signal. Try one change. Learn.

A CONCRETE EXAMPLE

Viewers repeat an inside joke in chat. Afterplay suggests opening the next stream with that callback, then checks whether more viewers return.

FIND

a callback viewers repeated in chat

TRY

open the next stream with that callback

LEARN

did more viewers come back or stay longer?

A creator can go from stream URL to approved test in one workspace.

AI turns channel history into one test.

WHERE AI CONTRIBUTES

The model reads evidence across streams, writes a testable plan, and later explains what the result should change. Code enforces approval and action rules.

CONNECT

history + current stream →
diagnosis

PLAN

diagnosis → hypothesis, clips,
and copy

LEARN

results → memory update and
next test

Three records guide each test.

The next test starts with evidence

Channel: recurring jokes, storylines, viewer quotes, and moments.

Audience: who returned, what they repeated, and when they left.

Market: what similar channels tried, which formats are growing, and where gaps remain.

■ AFTERPLAY

The screenshot shows a web interface titled 'Competitive intelligence' with a sub-header 'The channel brain'. Below the title, a description states: 'Afterplay watches your competitors continuously, measures what actually moves their reach, and remembers what it learns so every scan sharpens the last one.' A status bar shows '0 scans run', '0 videos analysed', '0 transcripts read', and '0 standing beliefs'. A red warning box indicates 'Scraper not configured' with the message: 'APIFY_API_TOKEN is not set, so a competitive scan cannot run. No sample report is substituted in its place.' The 'Configure the scan' section includes a 'YOUR CHANNEL' field with '@jackfrags' and a 'COMPETITORS (2/5)' list with '@LevelCapGaming' and '@Stodeh'. A '+ Add competitor' button is below. A 'VIDEOS PER CHANNEL' slider is set to 8, and a checked 'Read transcripts' checkbox is present. The 'WHICH VIDEOS TO SAMPLE' section has two options: 'Most recent' (selected) and 'All-time best'. At the bottom, it shows '3 channels · 24 videos' and '~\$0.12 scrape cost'. A 'LIVE DATA' status at the very bottom says: 'No scan has been run yet. Competitive intelligence needs a live scrape; no sample report is substituted.'

Each technical layer has one clear job.

IMPLEMENTED V1 ARCHITECTURE

A Next.js app owns the experiment lifecycle. A Python service handles media. Both return validated records that the creator can inspect.

MODEL

Responses API + strict output +
Zod

APP

Next.js 16 + TypeScript +
approval gates

CLIPPER

Python + ffmpeg + transcript
and callback scoring

Riff brings that history into the next live stream.

The prototype is already live

Riff follows gameplay, the creator, chat, and the approved experiment. When a useful moment arrives, it speaks, challenges the creator, or recalls a callback.

The working demo keeps simulated chat and scripted beats clearly labelled.

Expected impact: faster decisions, clearer learning.

TIME

hours from stream ingest to an approved test

CADENCE

approved experiments completed per month

RETURN

regular-viewer rate and repeat live visits

TRACE

recommendations linked to evidence and prior results

Future success measures. Baselines and targets come from creator data.

The working prototype already covers the full loop.

BEFORE

DURING

AFTER

Plan with context

Saved accounts, live platform data, creator history, and one approved experiment.

Riff joins live

Riff sees gameplay, hears the creator, reads chat, and speaks when the moment earns it.

Close the loop

Ingest, clipping, memory, approval, results, and the next experiment run end to end.

AFTERPLAY

**Afterplay helps gaming creators
learn what makes viewers come
back.**

Remember the channel.

Run the next test.

Learn from the result.
